

NowStream App Summary

Repo-based one-page overview

What It Is

NowStream is a Laravel 12 web platform for livestreaming and media distribution with event monetization. It serves livestreams, videos, TV/radio, podcasts, and tenant microsites through frontend, backend, and API routes.

Who It's For (Primary Persona)

Primary: event viewers/fans who purchase access and watch live or on-demand content. Secondary operators (admins/channel partners) manage channels, content, events, and transactions.

What It Does (Key Features)

- Browse/search streams, videos, podcasts, TV, radio, channels, categories, and events.
- Multi-tenant/subdomain microsites via tenant-aware routing and middleware.
- User auth flows: email login, phone OTP/login, social auth, profile/password management.
- Paid event subscriptions with M-Pesa and DPO, including payment callback handling.
- Stream access checks, tokenized subscriptions, and watch history/continue watching.
- Engagement tools: comments, likes/dislikes, favorites, and channel subscribe/unsubscribe.
- Admin backend CRUD for channels/content/events/rates/users/roles/transactions/configuration.

How It Works (Architecture from Repo Evidence)

- **Presentation:** Blade frontend (resources/views/Frontend/*) and backend admin (resources/views/Backend/*).
- **Routing:** routes/web.php, routes/admin.php, routes/api.php, plus payment callbacks in routes/mpesa.php and routes/dpo.php under /malipo.
- **Middleware:** country detection, tenant identification, auth/authorization, payment guards, API key/passkey checks (bootstrap/app.php).
- **Domain/data:** Eloquent models (Content, Subscription, Transaction, Event, Channel, User) with UUID keys and polymorphic comments/watch history.
- **Integrations:** M-Pesa, DPO, Africa's Talking SMS, Socialite OAuth, Sanctum token auth.
- **Async/events:** queued jobs (MpesaPaymentJob, VerifyTokenJob), events (PaymentFailed, NewComment), notifications (StreamKeyNotification).
- **Data flow:** Browser/API client to routes+middleware to controllers/services to MySQL/cache/queue to Blade HTML or JSON response.

How To Run (Minimal Getting Started)

1. Configure environment: copy `.env.example` to `.env` and set MySQL credentials (default DB name shown: `nowstream`).
2. Install/bootstrap: `run composer run setup` (installs PHP/Node deps, generates key, runs migrations, builds assets).
3. Start dev stack: `run composer run dev` (starts app server, queue listener, logs, and frontend build).
4. Open the app at configured `APP_URL` (default in `.env.example` is `http://localhost`).
